Intradural Disc Herniation-Transdural Excision

Farid Malik, Mangeet Singh, Tikoo Agnivesh, Dara Singh

Abstract

Intradural disc herniation (IDH) is a rare pathology. Once such case is presented with a discussion on diagnosis and management.

Key Words

Intradural Disc Herniation, Spinal Canal, Transdural

Introduction

Intradural disc herniation (IDH) is a rare pathology. Intradural disc herniations comprise 0.26-0.30% of all herniated discs. In all, 5% are found in the thoracic, 3% in the cervical, and 92% in the lumbar region (1, 2). The preoperative diagnosis of IDH is still difficult, despite new neuroradiologic investigation possibilities including computerized tomography (CT) and magnetic resonance imaging (MRI).

Case Report

A 55-year-old man suffered from decrease in the motor function of the lower extremities and urinary incontinence. At admission, neurological examination revealed; decrease in the motor function of the lower extremities in one-fifths, loss of patella and achilles tendon reflexes, and bladder dysfunction. Hypoesthesia of the left and right S1, L5 and L4 dermatomes were found. He had no back pain and Lasègue’s sign at 90°. Noncontrast
MRI exam showed the intradural disc with caudal migration of an excluded fragment at the L3-4 level. At surgery, the L3 and L4 laminas were removed and after dura had been opened, a nucleus pulposus was seen which compressed the conus medullaris to the right and left of the spinal canal. This disc material was removed with ceruful microdissection. The disc fragment had pierced the ventral wall of the dura. The postoperative course was uneventful and when seen again 4 months later, the patient was able to walk.

Discussion

Migration of the disc nucleus pulposus in the intradural site requires perforation of the annulus fibrosus of the posterior longitudinal ligament and the dura mater (3). The physiologic and pathological feature that cause this event are unclear, even though several reasons are known that may contribute to the formation of intradural herniation like congenital narrowing of the spinal canal with less epidural space, adhesions between the annulus fibrosus, posterior longitudinal ligament, duramater, congenital and iatrogenic fineness of the dura mater (1, 4, 5).

The treatment of intradural disc herniations basically involves surgical removal of ruptured disc material. At surgery, the dura and root must be carefully explored. Intradural disc need to be recognized and treated appropriately at the time of the initial operation to prevent the development of the back failure (6, 7). Cauda equina syndrome and sphincter disease have an incidence of 30% of all reported cases, as in our cases (1). However, there may be cases where the disc protrudes intradurally to compress a single root and show single only of root compression. Intradural disc herniation above the conus medullaris seems to bring on neurologic dysfunctions more rapidly (6). In the myelographic examination, intradural disc herniations of the lumbar region usually show as a complete block (8). Although CT and postmyelogram CT can provide valuable information regarding intradural lumbar disc herniation with MRI as reported by Epstein (2) and Jenkine (3). The MRI finding of an intradural lesion raises several diagnostic doubts that must be considered and resolved with differential diagnosis, which includes neurinoma, meningioma, ependymoma, and dermoid. Neurinoma and meningioma both have homogeneous enhancement and clearly different from the ring enhancement of intradural herniations. The site most frequently affected is L4-5 (55%), followed by L3-4 (16%) and L5-S1 (10%) (5, 9). Even more rarely, ruptured disc fragment may migrate intrathecally. According to the commonly admitted theory, this migration may be facilitated by the existence of adhesions between the posterior longitudinal ligament and the anterior ligament (3, 10).

As a result, during the disc operation, every neurosurgeon involved in spinal surgery must be aware of this rare pathology which, when overseen during the intervention, could have disastrous consequences for the patient.
